International Institute for Applied Systems Analysis (IIASA)

# **Externalities in the bottom-up energy system modeling framework**

Analyses with the MARKAL model

Expert Workshop on Energy and Climate Change Modeling 17th of November 2011 Seoul, Korea

#### Scope

Definition of externalities

Methodology for internalisation of external costs

Scenario results & sensitivities

Combining externalities with other policies

Insights from modelling experiments

#### Externalities and energy system

### I I A S A

#### External costs are introduced if

- the emissions from the energy system imply damages to the society
- the resulting costs are not included in the market price of energy

#### Internalisation of external costs intends to

- compensate for the health and environmental damages
- yield a full-cost pricing of energy services

#### Beside the air emissions, additional externality burdens are considered:

 solid and liquid wastes, risk of accidents, occupational exposure to hazardous substances, noise, others

#### Quantification and monetization of damages requires

- site-specific impact assessment of technologies
- comparisons between different energy chains and fuel cycles

#### External costs in the MARKAL framework

#### Different methods applicable:

- 1. Ex-post quantification of damages and valuation of impacts
  - no feedback into the optimisation
- 2. Externality charged to every unit of output

$$Z_{extern} = Z + \sum_{t} ExtCost_{t} * ypp * Q_{t} * (1+d)^{-1}$$

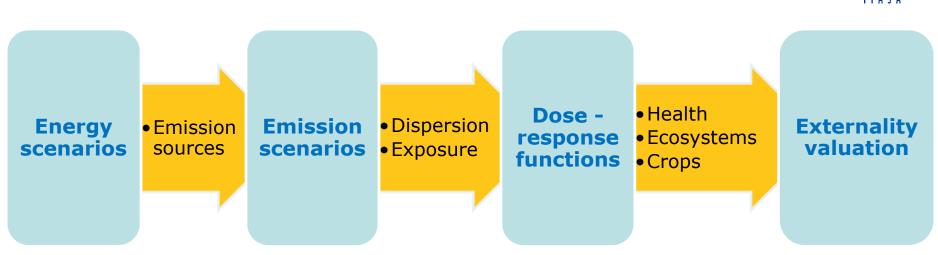

3. Damage function implying a tax on air emissions

$$DAM_{t,r} = \sum_{poll} DV_{t,r,poll} * EM_{t,r,poll}^{\beta}$$

## Economic Benefits of Climate Mitigation Policy Example India

#### Monetization of damages (€million/year)

| Baseline                    | 2030    |  |  |
|-----------------------------|---------|--|--|
| Ozone mortality             | 377     |  |  |
| Ozone morbidity             | 572     |  |  |
| PM <sub>2.5</sub> mortality | 227,442 |  |  |
| PM <sub>2.5</sub> morbidity | 86,655  |  |  |
| Total                       | 315,046 |  |  |

| Low carbon                  | 2030    |
|-----------------------------|---------|
| Ozone mortality             | 304     |
| Ozone morbidity             | 461     |
| PM <sub>2.5</sub> mortality | 185,314 |
| PM <sub>2.5</sub> morbidity | 70,605  |
| Total                       | 256,684 |
|                             |         |
| Co-benefit                  | 58,362  |

#### Integration in the Global Markal Model (GMM)

#### Main features

"Bottom-up" techno-economic model → Explicit representation of technologies

Optimisation under perfect foresight assumptions

Time horizon 2000-2050, 10-year steps

Partial equilibrium → Elastic demands

Energy system of five world regions

Multi-regional trading of selected commodities

Endogenous technological learning

Learning spill-over across regions

#### Internalisation of externalities in power sector

#### Basic assumptions

- External costs from local pollution (SO<sub>2</sub>, NO<sub>x</sub>, PM) and/or CO<sub>2</sub> internalized in the power sector
- External costs for each power plant in ¢/kWh derived from the EU ExternE-Project
- Externalities adjusted for regional differences in population density, fuel quality, power-plant efficiency and application of emissioncontrol systems

| Determinant for scaling                   | Unit                 | SO <sub>2</sub> | NO <sub>x</sub> | PM          | CO <sub>2</sub> |
|---|----------------------|-----------------|-----------------|-------------|-----------------|
| Average damage cost per pollutant         | € <sub>1995</sub> /t | 8000            | 7000            | 14000       | 19              |
| Population density adjustment factor (AF) | High                 | 1.5             | 1.5             | 1.5         |                 |
|   | Medium               | 1               | 1               | 1           | n.a.            |
|   | Low                  | 0.75            | 0.75            | 0.75        |                 |
| Reference thermal efficiency              |                      | coal            | oil             | natural gas |                 |
|   | %                    | 41              | 40              | 55          |                 |

#### Scaling of external costs

#### Options considered

#### 1. Population density

- NAME, EEFSU, LAFM Medium
- ASIA, OOECD High

#### 2. Improved conversion efficiency

$$ExtCost_{t} = ExtCost_{originalt=0} * \frac{\eta_{originalt=0}}{\eta_{t}}$$

#### 3. Welfare in regions (GDP/cap)

$$ExtCost_{t,r} = ExtCost_{originalt,r} * \frac{GDP_{ppp,t}^{r}}{GDP_{ppp,t=0}^{EU}}$$

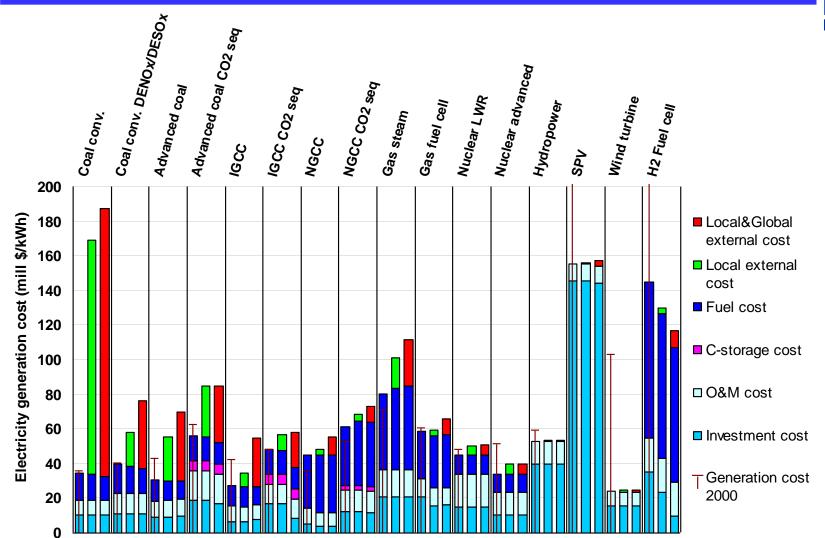

$$ExtCost_{t,r} = ExtCost_{originalt,r} * \frac{GDP_{mex,t}^{r}}{GDP_{mex,t=0}^{EU}}$$

| Technology   | External cost (cent/kWh) |      |                      |      |  |
|--|--------------------------|------|----------------------|------|--|
|  | excl CO <sub>2</sub>     |      | incl CO <sub>2</sub> |      |  |
| Fossil-fuel based power plants   | min                      | max  | min                  | max  |  |
| Coal conventional  | 8.1                      | 19.0 | 9.8                  | 20.8 |  |
| Coal conventional with DeSO <sub>x</sub> /DeNO <sub>x</sub>                  | 1.2                      | 1.8  | 2.9                  | 3.6  |  |
| Coal conv. with DeSO <sub>x</sub> /DeNO <sub>x</sub> and CO <sub>2</sub> seq | 1.5                      | 2.3  | 1.8                  | 2.9  |  |
| Coal advanced  | 1.6                      | 2.4  | 2.8                  | 3.8  |  |
| Coal advanced with CO <sub>2</sub> seq                                       | 1.8                      | 2.8  | 1.9                  | 3.0  |  |
| Coal IGCC  | 0.5                      | 1.0  | 2.2                  | 2.9  |  |
| Coal IGCC with CO <sub>2</sub> seq   | 0.6                      | 1.2  | 1.2                  | 1.7  |  |
| Natural Gas Combined Cycle (NGCC)  | 0.3                      | 1.1  | 8.0                  | 1.7  |  |
| NGCC with CO <sub>2</sub> sequestration                                      | 0.3                      | 1.3  | 0.7                  | 1.5  |  |
| Gas steam conventional   | 1.1                      | 3.0  | 1.9                  | 3.8  |  |
| Cogenaration gas turbine   | 1.2                      | 2.3  | 2.2                  | 3.3  |  |
| Oil conventional   | 1.3                      | 5.9  | 2.5                  | 7.2  |  |
| Non-fossil power plants  |                          |      |                      |      |  |
| Nuclear plant - Light Water Reactor (LWR)                                    | 0.5                      |      | 0.5                  |      |  |
| Hydro-electric plant (small and large)                                       | 0.1                      |      | 0.1                  |      |  |
| Solar photovoltaics (SPV)  | 0.1                      |      | 0.3                  |      |  |
| Wind turbine   | 0.1                      |      | 0.1                  |      |  |
| Biomass power plant  | 0.3                      |      | 0.4                  |      |  |
| Geothermal electric  | 0.1                      |      | 0.4                  |      |  |

#### Total electricity generation cost analysis

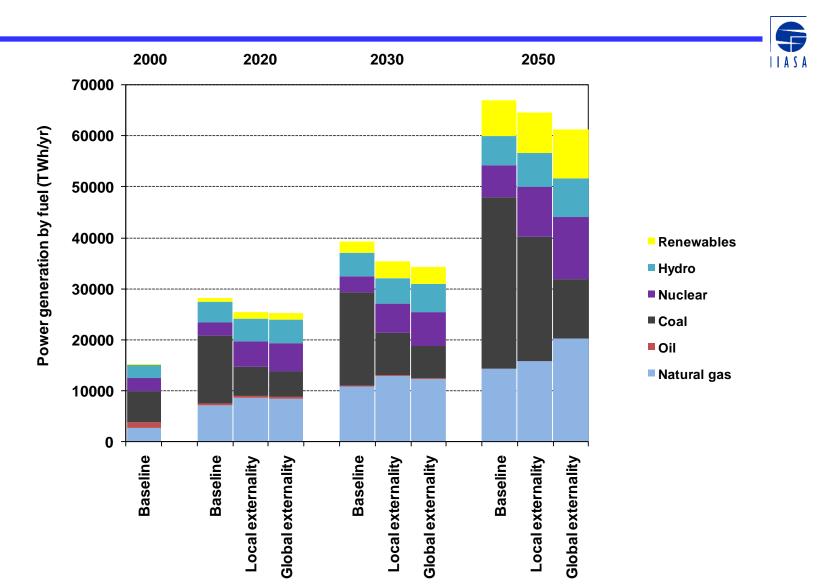

Example Asia, year 2050 
$$TGC = \frac{I*CRF}{Q} + \frac{FIXO \& M}{Q} + \frac{VARO \& M}{Q} + \frac{F}{Q} + \frac{F}{Q}$$

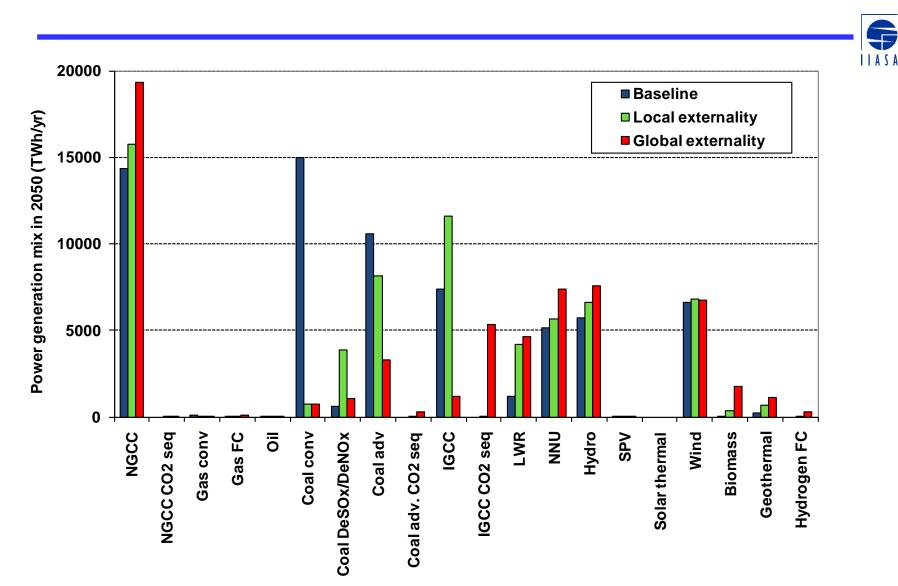

#### Development in global electricity production

Fuel mix changes due to integration of externalities

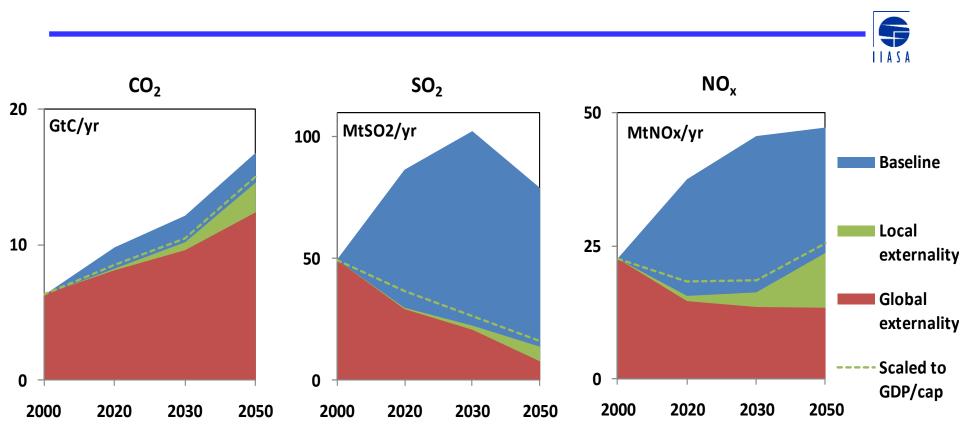

#### Impact on electricity generation profile

Technology portfolio in 2050

#### Global air emissions

CO<sub>2</sub> from all sources; SO<sub>2</sub>/NO<sub>x</sub> from power sector

 Alternative scaling of externalities with GDP results in lower cost penalty, still the impact on emissions is significant.

#### CO<sub>2</sub> emissions reduction components

Relative to the Baseline

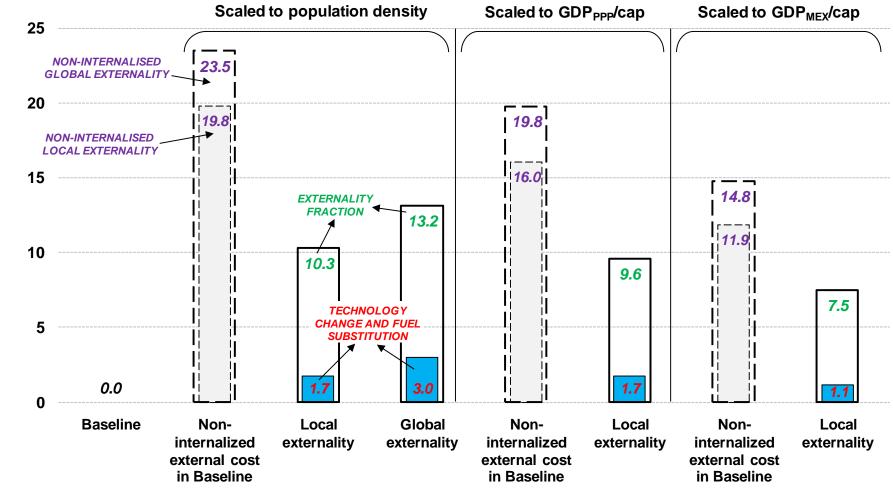

# Change in total system cost vs. Baseline (%)

#### Change in the cumulative energy system cost,

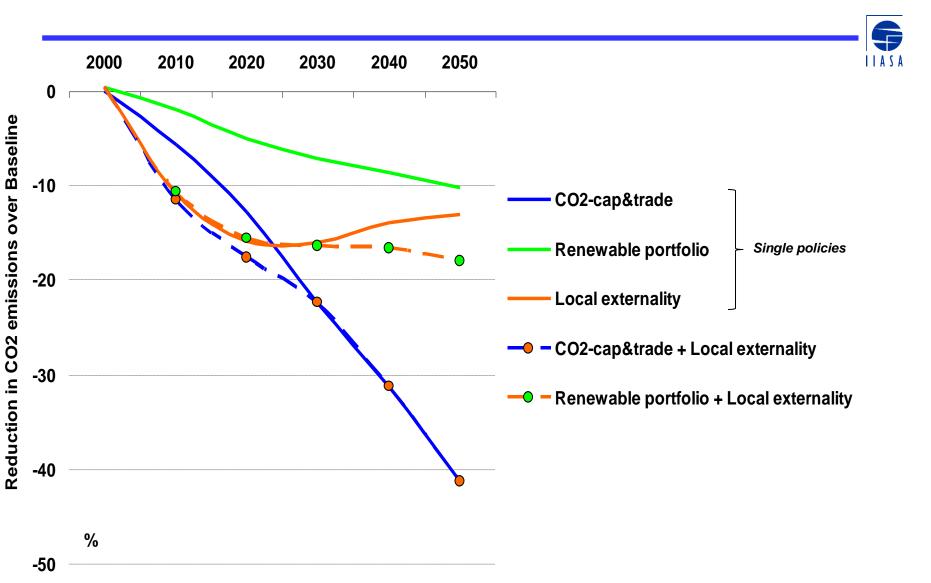

including external cost fraction

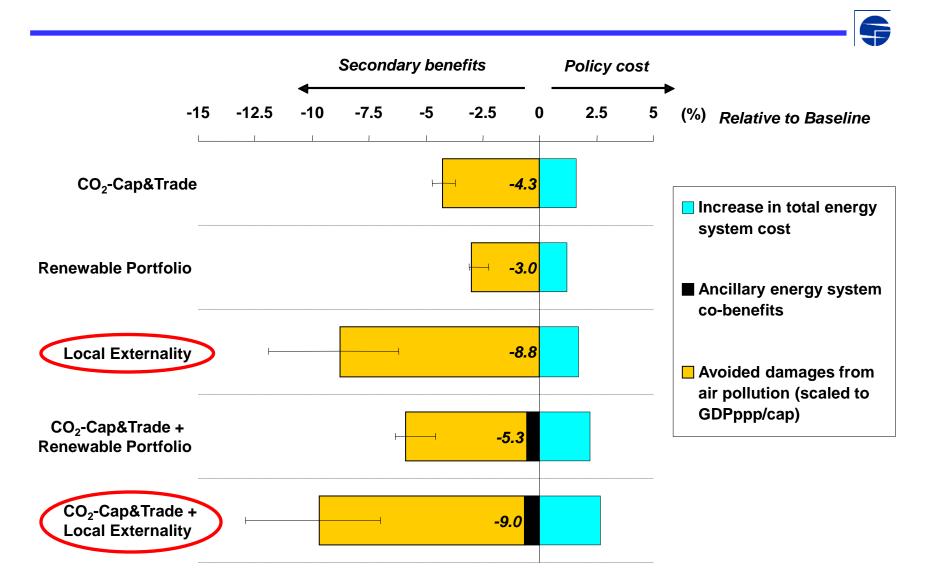

#### Synergies in combined policy adoption

Global CO<sub>2</sub> emission reductions

#### Cost and Benefit Assessment

#### Large uncertainties

#### Conclusions

- Monetary evaluation of the (co)benefits of emission control strategies provides relevant insights for decision makers
- Quantification of impacts based on MARKAL-inputs, but outside the optimization procedure, brings detailed assessment of a policy, when linked with dedicated air quality models (GAINS)
- Externalities integrated in the MARKAL's cost function allows to balance trade-offs between environmental ambition and the economic implications
- Modeling results indicate a large scope of co-benefits resulting from the parallel application of different policy instruments
- Monetization of health & environmental benefits are associated with a wide range of uncertainties and controversies
- If the externality analyses are used in an international policy context, it is challenging to attribute economic values to non-market goods: human life and ecosystems
